0.1. De winnende aanpak.

• Goed slapen & een vroeg ritme hebben
• Genoeg drinken & eten voor en tijdens de wedstrijd
• Een lijst van alle problemen met info waar het over gaat, en wie
```

- het goed kan oplossen

 Ludo moet ALLE opgaves goed lezen

 Test de kleine voorbeeldgevallen
- Houd na 2 uur een pauze en overleg waar iedereen mee bezig is
 Maak zelf wat test-cases
- Typ de dingen uit de TCR, die je zeker nodig hebt, alvast in
 Als iemand niks te doen heeft, kan hij nodige dingen uit de TCR
- We moeten ook een voorbeeld test-case voor TCR algoritmes hebben om te testen of het goed overgetypt is
- Bij geometrie moeten we om kunnen gaan met meerdere input manieren (voor bv. lijnen)
- Gebruik veel long long's

0.2. Wrong Answer.

- Print de oplossing om te debuggen! Kijk ook naar andere (mogelijk makkelijkere) problemen.
- (2) Bedenk zelf test-cases met randgevallen!
- (3) Controleer op overflow (gebruik OVERAL long long, long double).
 - Kijk naar overflows in tussenantwoorden bij modulo.
- 4) Controleer de **precisie**.
- (5) Controleer op typo's.
 (6) Loop de voorbeeldinput accuraat langs.
- (7) Controller op off-by-one-errors (in indices of lus-grenzen)?
- 0.3. **Detecting overflow.** These are GNU builtins, detect both overand underflow. Returns a boolean upon failure, otherwise the result fs present in ref. Follow the template:

bool isOverflown = __builtin_[add|mul|sub]_overflow(a, b, \&res);

0.4. Covering problems.

 $Minimum\ edge\ cover \iff Maximum\ independent\ set$

Matching: A set of edges without common vertices (Maximum is the largest such set, maximal is a set which you cannot add more edges to without breaking the property).

Minimum Vertex Cover: A set vertices (cover) such that each edge in the graph is incident to at least one vertex of the set.

Minimum Edge Cover: A set of edges (cover) such that every vertex

is incident to at least one edge of the set.

Maximum Independent Set: A set of vertices in a graph such that

Maximum Independent Set: A set of vertices in a graph such that
no two of them are adjacent.

**Essign theorem: In any hispartite graph, the number of edges in the set of the s

König's theorem: In any bipartite graph, the number of edges in a ming-maximum matching equals the number of vertices in a ming-mum vertex cover

0.5. Game theory. A game can be reduced to Nim if it is a finite impartial game. Nim and its variants include:

Nim: Let $X=\bigoplus_{i=1}^n x_i$, then $(x_i)_{i=1}^n$ is a winning position iff $X\neq \mathfrak{D}$. Find a move by picking k such that $x_k>x_k\oplus X$.

Misère Nim: Regular Nim, except that the last player to move loses.

Play regular Nim until there is only one pile of size larger than // returns x, y such that ax + by = gcd(a, b)

1, reduce it to 0 or 1 such that there is an odd number of piles. Il egcd(ll a, ll b, ll &x, ll &y) {

```
Staricase Nim: Stones are moved down a staircase and only removed
        from the last pile. (x_i)_{i=1}^n is an L-position if (x_{2i-1})_{i=1}^{n/2} is (i32.
        only look at odd-numbered piles).
Moore's Nim<sub>k</sub>: The player may remove from at most k piles (Nim^{3\pm}
        Nim<sub>1</sub>). Expand the piles in base 2, do a carry-less addition in
        base k+1 (i.e. the number of ones in each column should be
        divisible by k+1).
Dim<sup>+</sup>: The number of removed stones must be a divisor of the pile size.
        The Sprague-Grundy function is k+1 where 2^k is the largest
        power of 2 dividing the pile size.
Aliquot game: Same as above, except the divisor should be proper
        (hence 1 is also a terminal state, but watch out for size 0 piles).
        Now the Sprague-Grundy function is just k.
Nim (at most half): Write n+1=2^m y with m maximal, then the
        Sprague-Grundv function of n is (y-1)/2.
Lasker's Nim: Players may alternatively split a pile into two new
        non-empty piles. g(4k+1) = 4k+1, g(4k+2) = 4k+2,
        q(4k+3) = 4k+4, q(4k+4) = 4k+3 (k > 0).
Hackenbush on trees: A tree with stalks (x_i)_{i=1}^n may be replaced
        with a single stalk with length \bigoplus_{i=1}^{n} x_i.
   A useful identity: \bigoplus_{x=0}^{a-1} x = \{0, a-1, 1, a\} [a \mod 4].
                                                                  51

- 3.17. Maximum Density Subgraph. Given (weighted) undirected graph G. Binary search density. If g is current density, construct $\hat{\text{How}}$ network: (S, u, m), $(u, T, m + 2g - d_u)$, (u, v, 1), where m is a large constant (larger than sum of edge weights). Run floating-point maxflow. If minimum cut has empty S-component, then maximum density is smaller than g, otherwise it's larger. Distance between valid densities is at least 1/(n(n-1)). Edge case when density is 0. This also works for weighted graphs by replacing d_u by the weighted degree, and doing more iterations (if weights are not integers).
- 3.18. Maximum-Weight Closure. Given a vertex-weighted directed graph G. Turn the graph into a flow network, adding weight ∞ to each edge. Add vertices S, T. For each vertex v of weight w, add edge (S, v, u_2) if w > 0, or edge (v, T, -w) if w < 0. Sum of positive weights minus minimum S-T cut is the answer. Vertices reachable from S are in the closure. The maximum-weight closure is the same as the complement of the minimum-weight closure on the graph with edges reversed.
- 3.19. Maximum Weighted Independent Set in a Bipartite **Graph.** This is the same as the minimum weighted vertex cover. Solve this by constructing a flow network with edges (S, u, w(u)) for $u \in \mathcal{L}$, (v,T,w(v)) for $v\in R$ and (u,v,∞) for $(u,v)\in E$. The minimum S,Tcut is the answer. Vertices adjacent to a cut edge are in the vertex cover.
- 3.20. Synchronizing word problem. A DFA has a synchronizing word (an input sequence that moves all states to the same state) iff. each pair of states has a synchronizing word. That can be checked using reverse DFS over pairs of states. Finding the shortest synchronizing word is NP-complete.

```

8. Useful Information

9. Misc

9.1. Debugging Tips.

- Stack overflow? Recursive DFS on tree that is actually a long path?
- Floating-point numbers
 - Getting NaN? Make sure acos etc. are not getting values out of their range (perhaps 1+eps).
 - Rounding negative numbers?
 - Outputting in scientific notation?
- Wrong Answer?
 - Read the problem statement again!
 - Are multiple test cases being handled correctly? Try repeating the same test case many times.
 - Integer overflow?
 - Think very carefully about boundaries of all input parameters
 - Try out possible edge cases:
 - * $n = 0, n = -1, n = 1, n = 2^{31} 1$ or $n = -2^{31}$
 - * List is empty, or contains a single element
 - * n is even, n is odd
 - * Graph is empty, or contains a single vertex
 - * Graph is a multigraph (loops or multiple edges)
 - * Polygon is concave or non-simple
 - Is initial condition wrong for small cases?
 - Are you sure the algorithm is correct?
 - Explain your solution to someone.
 - Are you using any functions that you don't completely understand? Maybe STL functions?
 - Maybe you (or someone else) should rewrite the solution?
 - Can the input line be empty?
- Run-Time Error?
 - Is it actually Memory Limit Exceeded?

9.2. Solution Ideas.

- Dynamic Programming
 - Parsing CFGs: CYK Algorithm
 - Drop a parameter, recover from others
 - Swap answer and a parameter
 - When grouping: try splitting in two
 - -2^k trick
 - When optimizing
 - * Convex hull optimization
 - $\cdot \operatorname{dp}[i] = \min_{j < i} \{\operatorname{dp}[j] + b[j] \times a[i]\}$
 - b[j] > b[j+1]
 - · optionally a[i] < a[i+1]
 - · $O(n^2)$ to O(n)
 - * Divide and conquer optimization
 - $dp[i][j] = \min_{k < j} \{dp[i-1][k] + C[k][j]\}$
 - $A[i][j] \le A[i][j+1]$
 - · $O(kn^2)$ to $O(kn\log n)$
 - · sufficient: $C[a][c] + C[b][d] \le C[a][d] + C[b][c]$, $a \le b \le c \le d$ (QI)
 - * Knuth optimization
 - $dp[i][j] = \min_{i < k < j} \{dp[i][k] + dp[k][j] + C[i][j]\}$
 - $A[i][j-1] \le A[i][j] \le A[i+1][j]$
 - $O(n^3)$ to $O(n^2)$

- · sufficient: QI and $C[b][c] \leq C[a][d], a \leq b \leq c \leq d$
- Greedy
- Randomized
- Optimizations
 - Use bitset (/64)
 - Switch order of loops (cache locality)
- Process queries offline

 - Implicit
 - Segment tree of X
- Geometry
 - Minkowski sum (of convex sets)
 - Rotating calipers
 - Sweep line (horizontally or vertically?)
 - Sweep angle
 - Convex hull
- Fix a parameter (possibly the answer).
- Are there few distinct values?
- Binary search
- Sliding Window (+ Monotonic Queue)
- Computing a Convolution? Fast Fourier Transform
- Computing a 2D Convolution? FFT on each row, and then on each
- Exact Cover (+ Algorithm X)
- Cycle-Finding
- What is the smallest set of values that identify the solution? The cycle structure of the permutation? The powers of primes in the factorization?
- Look at the complement problem

- Minimize something instead of maximizing
- Immediately enforce necessary conditions. (All values greater than 0? Initialize them all to 1)
- Add large constant to negative numbers to make them positive
- Counting/Bucket sort

10. Formulas

- Legendre symbol: $(\frac{a}{b}) = a^{(b-1)/2} \pmod{b}$, b odd prime.
- Heron's formula: A triangle with side lengths a, b, c has area $\sqrt{s(s-a)(s-b)(s-c)}$ where $s=\frac{a+b+c}{2}$.
- Pick's theorem: A polygon on an integer grid strictly containing i lattice points and having b lattice points on the boundary has area $i+\frac{b}{2}-1$. (Nothing similar in higher dimensions)
- Euler's totient: The number of integers less than n that are coprime to n are $n \prod_{p|n} \left(1 - \frac{1}{n}\right)$ where each p is a distinct prime factor of n.
- König's theorem: In any bipartite graph $G = (L \cup R, E)$, the number of edges in a maximum matching is equal to the number of vertices in a minimum vertex cover. Let U be the set of unmatched vertices in L, and Z be the set of vertices that are either in U or are connected to U by an alternating path. Then $K = (L \setminus Z) \cup (R \cap Z)$ is the minimum
- A minumum Steiner tree for n vertices requires at most n-2 additional Steiner vertices.
- The number of vertices of a graph is equal to its minimum vertex cover number plus the size of a maximum independent set.
- Lagrange polynomial through points $(x_0, y_0), \dots, (x_k, y_k)$ is $L(x) = \sum_{j=0}^{k} y_j \prod_{0 \le m \le k} \frac{x - x_m}{x_j - x_m}$
- Hook length formula: If λ is a Young diagram and $h_{\lambda}(i,j)$ is the hook-length of cell (i, j), then then the number of Young tableux $d_{\lambda} = n! / \prod h_{\lambda}(i,j).$
- Möbius inversion formula: If $f(n) = \sum_{d|n} g(d)$, then $g(n) = \sum_{d|n} g(d)$ $\sum_{d|n} \mu(d) f(n/d). \quad \text{If } f(n) = \sum_{m=1}^{n} g(\lfloor n/m \rfloor), \text{ then } g(n) = \sum_{m=1}^{n} g(\lfloor n/m \rfloor)$ $\sum_{m=1}^{n} \mu(m) f(\lfloor \frac{n}{m} \rfloor)$.
- #primitive pythagorean triples with hypotenuse < n approx $n/(2\pi)$.
- Frobenius Number: largest number which can't be expressed as a linear combination of numbers a_1, \ldots, a_n with non-negative coefficients. $g(a_1, a_2) = a_1 a_2 - a_1 - a_2$, $N(a_1, a_2) = (a_1 - 1)(a_2 - 1)/2$. $g(d \cdot a_1, d \cdot a_2, a_3) = d \cdot g(a_1, a_2, a_3) + a_3(d-1)$. An integer $x > a_3$ $(\max_i a_i)^2$ can be expressed in such a way iff. $x \mid \gcd(a_1, \ldots, a_n)$.

10.1. Physics.

- Snell's law: $\frac{\sin \theta_1}{v_1} = \frac{\sin \theta_2}{v_2}$
- 10.2. Markov Chains. A Markov Chain can be represented as a weighted directed graph of states, where the weight of an edge represents the probability of transitioning over that edge in one timestep. Let $P^{(m)} = (p_{ij}^{(m)})$ be the probability matrix of transitioning from state i to state j in m timesteps, and note that $P^{(1)}$ is the adjacency matrix of the graph. Chapman-Kolmogorov: $p_{ij}^{(m+n)} = \sum_k p_{ik}^{(m)} p_{kj}^{(n)}$. It follows that $P^{(m+n)} = P^{(m)}P^{(n)}$ and $P^{(m)} = P^m$. If $p^{(0)}$ is the initial probability distribution (a vector), then $p^{(0)}P^{(m)}$ is the probability distribution after m timesteps.

odic if $gcd(R_i) = 1$. A MC is aperiodic if any of its vertices is aperiodic. A MC is *irreducible* if the corresponding graph is strongly connected.

A distribution π is stationary if $\pi P = \pi$. If MC is irreducible then $\pi_i = 1/\mathbb{E}[T_i]$, where T_i is the expected time between two visits at i. π_i/π_i is the expected number of visits at j in between two consecutive visits at i. A MC is ergodic if $\lim_{m\to\infty} p^{(0)}P^m = \pi$. A MC is ergodic iff, it is irreducible and aperiodic.

A MC for a random walk in an undirected weighted graph (unweighted graph can be made weighted by adding 1-weights) has $p_{uv} = w_{uv}/\sum_x w_{ux}$. If the graph is connected, then $\pi_u =$ $\sum_x w_{ux}/\sum_v \sum_x w_{vx}$. Such a random walk is aperiodic iff. the graph is not bipartite.

An absorbing MC is of the form $P = \begin{pmatrix} Q & R \\ 0 & I_r \end{pmatrix}$. Let N = $\sum_{m=0}^{\infty} Q^m = (I_t - Q)^{-1}$. Then, if starting in state i, the expected number of steps till absorption is the i-th entry in N1. If starting in state i, the probability of being absorbed in state i is the (i, j)-th entry of NR.

Many problems on MC can be formulated in terms of a system of recurrence relations, and then solved using Gaussian elimination.

10.3. Burnside's Lemma. Let G be a finite group that acts on a set X. For each g in G let X^g denote the set of elements in X that are fixed by q. Then the number of orbits

$$|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|$$

$$Z(S_n) = \frac{1}{n} \sum_{l=1}^{n} a_l Z(S_{n-l})$$

10.4. **Bézout's identity.** If (x,y) is any solution to ax + by = d (e.g. found by the Extended Euclidean Algorithm), then all solutions are given

$$\left(x + k \frac{b}{\gcd(a,b)}, y - k \frac{a}{\gcd(a,b)}\right)$$

10.5. Misc.

10.5.1. Determinants and PM.

$$\begin{split} \det(A) &= \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) \prod_{i=1}^n a_{i,\sigma(i)} \\ perm(A) &= \sum_{\sigma \in S_n} \prod_{i=1}^n a_{i,\sigma(i)} \\ pf(A) &= \frac{1}{2^n n!} \sum_{\sigma \in S_{2n}} \operatorname{sgn}(\sigma) \prod_{i=1}^n a_{\sigma(2i-1),\sigma(2i)} \\ &= \sum_{M \in \operatorname{PM}(n)} \operatorname{sgn}(M) \prod_{(i,j) \in M} a_{i,j} \end{split}$$

10.5.2. BEST Theorem. Count directed Eulerian cycles. Number of OST given by Kirchoff's Theorem (remove r/c with root) #OST(G,r). $\prod_{v} (d_v - 1)!$

The return times of a state i is $R_i = \{m \mid p_{ii}^{(m)} > 0\}$, and i is aperi- 10.5.3. Primitive Roots. Only exists when n is $2, 4, p^k, 2p^k$, where p odd prime. Assume n prime. Number of primitive roots $\phi(\phi(n))$ Let q be primitive root. All primitive roots are of the form g^k where $k, \phi(p)$ are

k-roots: $q^{i \cdot \phi(n)/k}$ for $0 \le i \le k$

10.5.4. Sum of primes. For any multiplicative f:

$$S(n,p) = S(n,p-1) - f(p) \cdot (S(n/p,p-1) - S(p-1,p-1))$$

10.5.5. Floor.

$$\lfloor \lfloor x/y \rfloor / z \rfloor = \lfloor x/(yz) \rfloor$$
$$x\%y = x - y \mid x/y \mid$$

PRACTICE CONTEST CHECKLIST

- How many operations per second? Compare to local machine.
- What is the stack size?
- How to use printf/scanf with long long/long double?
- Are __int128 and __float128 available?
- Does MLE give RTE or MLE as a verdict? What about stack overflow?
- What is RAND_MAX?
- How does the judge handle extra spaces (or missing newlines) in the output?
- Look at documentation for programming languages.
- Try different programming languages: C++, Java and Python.
- Try the submit script.
- Try local programs: i?python[23], factor.
- Try submitting with assert(false) and assert(true).
- Return-value from main.
- Look for directory with sample test cases.
- Make sure printing works.
- Remove this page from the notebook.
